

APPLICATION

Novel Screening Approach for the Separation of Pharmaceutical Compounds using Lux® Polysaccharide-Based Chiral Stationary Phases in SFC Mode

Richard Hodgson¹, Michael Klein², and Marc Jacob²

Phenomenex LTD, Queens Avenue, Hurdsfield Industrial Estate, Macclesfield, Cheshire, SK10BN, United Kingdom

In this technical note, we report a novel screening approach for the chiral chromatographic separation, derived from a 56 pharmaceutical compound test set, using five Lux polysaccharide-based chiral stationary phases in supercritical fluid chromatography mode within an analysis time of 30 min or less.

Introduction

Of the many techniques available for the separation of enantiomers, high performance liquid chromatography (HPLC) using polysaccharide-based chiral stationary phases (CSP) is currently the most popular.^{1,2} Some of the reasons for this include ease of use, high success rate, and ability to scale to preparative separations.³

However, over the past few years supercritical fluid chromatography (SFC) has regained interest as a valuable alternative chromatographic technique for chiral separations. The supercritical mobile phase, which typically is constituted of a large percentage of carbon dioxide (>60%), has a higher diffusivity and lower viscosity than liquid chromatography mobile phases. As a result, it is possible to run instruments at higher flow rates, which enables higher throughput by a reduction in column equilibration and

Table 1. Fifty-six racemic pharmaceutical compounds screened in this study

Compounds	Compounds	Compounds

Ephedrine	Nimodipine	V era pamil		
Esmolol	Nisoldipine	Warfarin		
Fenoprofen	Nitrendipine			

Acidic compounds are written in italic

analysis times. In addition, SFC results in lowering consumption of organic solvent, decreasing costs, and reducing environmental impact.⁴

With increasing workloads and decreasing resources, fast and efficient chiral method development screening strategies are required to save development time. In this technical note, we wish to report the screening strategy, derived from a representative group of 56 chiral pharmaceutical compounds (**Table 1**) using five Lux polysaccharide-based CSPs (**Table 2**) under SFC conditions.

The results summarized in this application are extracted from an extended study performed by De Klerck *et al.*⁵ For all results and explanations, we recommend the reader to consult the recent published article from this group as well as the references cited therein.

Table 2. Lux chiral phases used in this study

Column Name	Phase Description
Lux Cellulose-1	Cellulose tris(3,5-dimethylphenylcarbamate)
Lux Cellulose-2	Cellulose tris(3-chloro-4-methylphenylcarbamate)
Lux Cellulose-3	Cellulose tris(4-methylbenzoate)
Lux Cellulose-4	Cellulose tris(4-chloro-3-methylphenylcarbamate)
Lux Amylose-2	Amylose tris(5-chloro-2-methylphenylcarbamate)

Material and Methods

The analyses shown in this technote were performed using an analytical SFC method station from Thar Instruments (Pittsburgh, PA, USA, a Waters® company) equipped with a Waters 2998-DAD detector (Milford, MA, USA). Data acquisition and processing were performed using ChromScope™ V1.10 software (2011) from Waters. The columns used for analysis: Lux Cellulose-1 (Cell-1), Cellulose-2 (Cell-2), Cellulose-3 (Cell-3), Cellulose-4 (Cell-4), and Amylose-2 (Amy-2) were obtained from Phenomenex (Torrance, CA, USA). All columns had dimensions 250 x 4.6 mm I.D. and 5 µm particle size. SFC conditions unless noted otherwise were the following: flow rate: 3 mL/min, temperature: 30 °C, detection: UV @ 220 nm, backpressure: 150 bar, injection volume: 5 µL, run time: 30 min. Compounds that did not elute (entirely) within the set time frame of 30 minutes are considered as non-eluted. All solutions were prepared at sample concentration of 0.5 mg/mL in methanol (MeOH). Pharmaceutical compounds and materials were purchased from various suppliers (see reference 5 for further details).

²Phenomenex, Inc., 411 Madrid Ave., Torrance, CA 90501 USA

Results and Discussion

The test group of 56 racemic pharmaceutical compounds listed in **Table 1** was screened on five Lux® polysaccharide-based CSPs (Cellulose-1, Cellulose-2, Cellulose-3, Cellulose-4, and Amylose-2) with eight mobile phases under SFC conditions. The SFC mobile phases tested in this study are described in **Table 3**.

Table 3. SFC mobile phases used in this study

MP	Description
A	CO ₂ /(MeOH with 0.5 % additive) 90/10
В	CO ₂ /(MeOH with 0.5 % additive) 80/20
С	CO ₂ /(MeOH with 0.25 % IPA and 0.25 % TFA) 90/10
D	CO ₂ /(MeOH with 0.1 % IPA and 0.1 % TFA) 80/20
E	CO ₂ /(2PrOH with 0.5 % additive) 90/10
F	CO ₂ /(2PrOH with 0.5 % additive) 90/10
G	CO ₂ /(2PrOH with 0.25 % IPA and 0.25 % TFA) 90/10
Н	CO ₂ /(2PrOH with 0.1 % IPA and 0.1 % TFA) 80/20

MP = mobile phase, MeOH = methanol, 2PrOH = isopropanol/ 2-propanol, TFA = trifluoroacetic acid, IPA = isopropylamine. For acidic compounds, additive was TFA and for all other compounds (neutral, amphoteric, basic) IPA was used as additive.

The number of baseline separations (Rs > 1.5) with the five commercially available Lux CSPs are summarized in **Figure 1** for each mobile phase condition. For this set of 56 pharmaceutical compounds, Lux Cellulose-1, Cellulose-2, and Cellulose-4 returned the highest number of baseline separations for mobile phases B, D, F, and H. Lux Cellulose-1 showed the largest number of base-line separations for five of the eight mobile phases tested. The mobile phases showing the highest number of baseline separations were D and H. Both of these mobile phases contain a high concentration of organic solvent (20 %) and a combination of acidic (0.1% TFA) and basic (0.1% IPA) additives.

The increase in the number of baseline separations for mobile phases D and H is related to a decrease in retention time, resulting in elution (and separation) of a number of analytes that were eluting outside the 30 minute time window with weaker mobile phases. In addition, peaks were sharper when using higher modifier concentrations, resulting in slightly higher resolutions.

The cumulative baseline separations for the five Lux polysac-charide-based chiral columns using a mobile phase of $\mathrm{CO}_2/\mathrm{(MeOH\ with\ 0.1\%\ IPA\ and\ 0.1\%\ TFA)}$, 80/20, v/v (D) is shown in **Figure 2**. Using this mobile phase, the baseline separations from the most successful CSP are recorded first. Then the second CSP is selected based on the highest number of added unique base-line separations compared with the first, followed by the third, fourth, and then fifth. Using this strategy, 46 of the 56 pharmaceutical compounds are baseline separated using mobile phase D and all five Lux CSPs.

Figure 2. Cumulative baseline separations across five Lux phases using mobile phase of CO $_7$ (MeOH with 0.1% IPA and 0.1% TFA), 80/20 v/v (D)

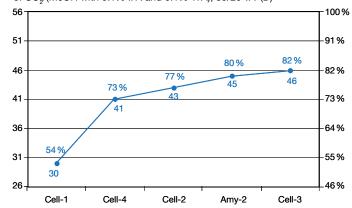

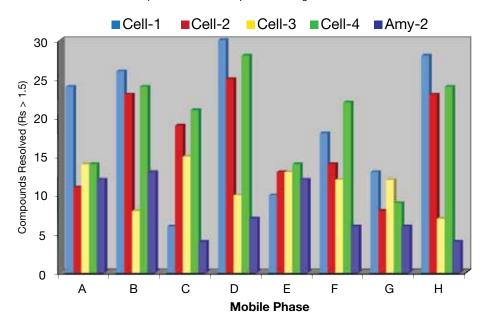

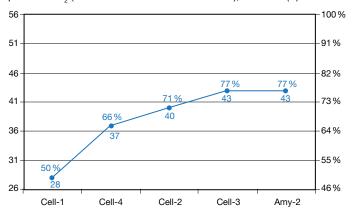

Figure 1.Number of baseline separations for mobile phase A through H

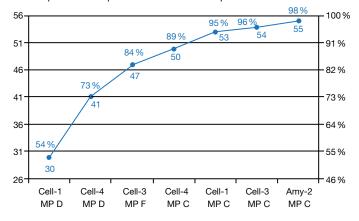

The cumulative baseline separations of the five Lux polysaccharide-based chiral columns using a mobile phase of CO₂/(2PrOH with 0.1% IPA and 0.1% TFA), 80/20, v/v (H) are shown in Figure 3. In the same way as before, 43 of the 56 pharmaceutical compounds are baseline resolved. In fact, only four CSPs are needed to obtain the maximal success rate.

Figure 3. Cumulative baseline separations across five Lux® phases using mobile phase of CO₂/(2PrOH with 0.1% IPA and 0.1% TFA), 80/20 v/v (H)

By using 7 chromatographic systems, which require three mobile phases (C, D, and F) and four Lux CSPs (Cellulose-1, Cellulose-3. Cellulose-4, and Amylose-2), 55 of the 56 test group compounds are baseline separated (Figure 4).

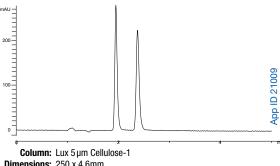

Figure 4. Cumulative baseline separations across seven chromatographic systems made up of four Lux phases and three mobile phases

In Figures 5a and 5b, some typical SFC separations are represented. All chiral separations with resolutions greater than 1.5 can be found on our application search webpage www.phenomenex. com/Application/Search.

Chiral separation of Alprenolol by SFC

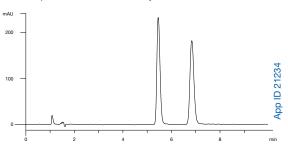

Dimensions: 250 x 4.6mm Part No.: 00G-4459-E0

Mobile Phase: CO₂/(Methanol + 0.5 % IPA) 80:20 (v/v) (B)

Flow Rate: 3 mL/min Temperature: 30 °C

Figure 5b.

Chiral separation of Mianserine by SFC

Column: Lux 5 µm Cellulose-4 Dimensions: 250 x 4.6mm Part No.: 00G-4451-E0

Mobile Phase: CO_2 /(Methanol + 0.1% IPA + 0.1% TFA) 80:20 (v/v) (H)

Flow Rate: 3 mL/min Temperature: 30 °C

Conclusion

The results from this study clearly suggest the complexity of chiral screening under SFC conditions and the differences which can occur with relatively small changes in mobile phase composition. In particular, the influence of additives on the polysaccharide-based chiral stationary phases is yet to be fully understood. For the selected mixture of 56 racemic pharmaceutical compounds, we have demonstrated that screening with a single, well-selected mobile phase and four or five Lux polysaccharide based CSPs can give a high probability of baseline separation.
